Starting with basic definitions in signal theory, the text explains the properties of continuous-time and discrete-time systems and their representation by differential equations and state space. From those tools, explanations for the processes of Fourier analysis, the Laplace transform, and the z-Transform provide new ways of experimenting with different kinds of time systems. The text also covers the separate classes of analog filters and their uses in signal processing applications. Intended for undergraduate electrical engineering students, chapter sections include exercise for review and practice for the systems concepts of each chapter. Along with exercises, the text includes MATLAB-based examples to allow readers to experiment with signals and systems code on their own. This book is on the iterative learning control (ILC) with focus on the design and implementation. We approach the ILC design based on the frequency domain analysis and address the ILC implementation based on the sampled data methods. This is the first book of ILC from frequency domain and sampled data methodologies. The frequency domain design methods offer ILC users insights to the convergence performance which is of practical benefits. This book presents a comprehensive framework with various methodologies to ensure the learnable bandwidth in the ILC system to be set with a balance between learning performance and learning stability. The sampled data implementation ensures effective execution of ILC in practical dynamic systems. The presented sampled data ILC methods also ensure the balance of performance and stability of learning process. Furthermore, the presented theories and methodologies are tested with an ILC controlled robotic system. The experimental results show that the machines can work in much higher accuracy than a feedback control alone can offer. With the proposed ILC algorithms, it is possible that machines can work to their hardware design limits set by sensors and actuators. The target audience for this book includes scientists, engineers and practitioners involved in any systems with repetitive operations.

The main purpose of this thesis focuses on the investigation of the frequency domain analysis and design approaches for nonlinear damping systems. With the development of modern mechanical and civil engineering structures, the vibration control has become a more and more important problem for the structural system protection. As typical energy dissipation equipments for the structural vibration control purpose, damping devices have been designed and fitted in many modern structural systems. Traditional frequency domain design methods for linear damping devices have been widely studied by engineers and applied in engineering practice, where the system output frequency response is equal to the input spectrum multiplied by the system frequency response function. Recently, nonlinear damping devices have received more and more attentions and been applied in practical engineering systems to overcome the limitations of linear damping devices in the system vibration control. The analysis and design of nonlinear systems, however, are far more complicated than the design of linear systems. The frequency domain design methods for linear systems cannot easily be extended to the nonlinear cases. Traditional frequency domain analysis and design methods for nonlinear systems involve complicated computations, and are, consequently, difficult to be applied in practice. Therefore, more effective frequency domain analysis and design approaches should be developed to facilitate the design of nonlinear damping devices and to satisfy the demand for better vibration performance in practical engineering structural systems. Motivated by this requirement, several new frequency domain analysis and design approaches have been proposed for the analysis of the performance and the design of the characteristic parameters of nonlinear viscous damping devices. The main contributions of the research work can be summarized as follows. (1) Based on the Ritz-Galerkin method, a new method for the evaluation of the transmissibility of nonlinear SDOF viscously damped vibration systems under general harmonic excitations is derived. The effects of damping characteristic parameters on the system transmissibility are investigated. The results reveal that properly designed nonlinear fluid viscous dampers can produce more ideal vibration control over a wide frequency range. (2) The Output Frequency Response Function (OFRF) is a concept recently proposed at Sheffield for the analysis and design of nonlinear systems in the frequency domain. Based on the OFRF, a frequency domain analysis and design approach has been developed to study the impact of additional nonlinear viscous damping devices on the vibration isolation behaviours of MDOF viscously damped vibration systems, and to design the characteristic parameters of additional damping devices for a desired system vibration performance. (3) Based on the OFRF, a new concept called Vibration Power Loss Factor (VPLF) is proposed to evaluate the effects of additional fluid viscous dampers on the vibration control of structural systems subjected to general loading excitations. A novel VPLF and OFRF based approach is then proposed for the design of additional fluid viscous dampers to achieve a desired vibration performance when the structural systems are subject to general loading excitations. The advantages of using different types of additional fluid viscous dampers in structural systems for the vibration control purpose are also investigated. (4) Using the Finite Element (FE) model analyses, the effectiveness of the application of the proposed OFRF and VPLF based frequency domain design approaches in the design of additional fluid viscous dampers for the vibration control in more complicated structural systems has been verified. The frequency domain analysis and design approaches proposed in this thesis provide a significant basis and important guidelines for the analysis and design of a wide class of nonlinear viscously damped engineering structural systems. The results reveal the advantages of additional nonlinear viscous damping devices in the system vibration control and have considerable significance for the design of the damping characteristic parameters to achieve a desired system vibration performance.

Vibration is a phenomenon that we can perceive in many systems. Their effects are as diverse as the personal discomfort that can produce the unevenness of a road or the collapse of a building or a bridge during an earthquake. This book is a compendium of research works on vibration analysis and control. It goes through new methodologies that help us understand and mitigate this phenomenon. This book is divided into two sections. The first one is devoted to new advances on vibration analysis while the second part is a series of case studies that illustrate novel techniques on vibration control. The applications are varied and include areas such as vehicle suspension systems, wind turbines and civil engineering structures.

The book serves to be both a textbook and a reference for the theory and laboratory courses offered to undergraduate and graduate engineering students, and for practicing engineers.

This book is a systematic summary of some new advances in the area of nonlinear analysis and design in the frequency domain, focusing on the application oriented theory and methods based on the GFRF concept, which is mainly done by the author in the past 8 years. The main results are formulated uniformly with a parametric characteristic approach, which provides a convenient and novel insight into nonlinear influence on system output response in terms of characteristic parameters and thus facilitate nonlinear analysis and design in the frequency domain. The book starts with a brief introduction to the background of nonlinear analysis in the frequency domain, followed by recursive algorithms for computation of GFRFs for different parametric models, and nonlinear output frequency properties. Thereafter the parametric characteristic analysis method is introduced, which leads to the new understanding and formulation of the GFRFs, and nonlinear characteristic output spectrum (nCOS) and the nCOS based analysis and design method. Based on the parametric characteristic approach, nonlinear influence in the frequency domain can be investigated with a novel insight, i.e., alternating series, which is followed by some application results in vibration control. Magnitude bounds of frequency response functions of nonlinear systems can also be studied with a parametric characteristic approach, which result in novel parametric convergence criteria for any given parametric nonlinear model whose input-output relationship allows a convergent Volterra series expansion. This book targets those readers who are working in the areas related to nonlinear analysis and design, nonlinear signal processing, nonlinear system identification, nonlinear vibration control, and so on. It

particularly serves as a good reference for those who are studying frequency domain methods for nonlinear systems.

Over the past decade, considerable effort has been devoted to the analysis and design of feedback controllers for systems characterized by uncertain dynamic descriptions, and both frequency-domain and time-domain techniques have been produced by these studies. In this document, additional aspects of the analysis and design problems are investigated. Techniques are derived to enhance the frequency-domain analysis of perturbed systems and to generalize the time-domain concept of self-tuning control to multivariable systems. The first part of this document addresses the problem of generating an accurate description of frequency response uncertainty for systems whose models are generated via system identification. Finite weighting sequence models are found to be particularly useful for this purpose. Techniques are derived to quantify the variability of the frequency response estimates associated with the given model, to identify the optimal truncation level for the specified identification test, and to assess the impact of the bias introduced by truncation. The second part considers the use of multivariable weighting sequences in the development of on-line computer-implemented control algorithms.

This book focuses on the development of three novel approaches to build up a framework for the frequency domain analysis and design of nonlinear systems. The concepts are derived from Volterra series representation of nonlinear systems which are described by nonlinear difference or differential equations. Occupying the middle ground between traditional linear approaches and more complex nonlinear system theories, the book will help readers to have a good start to analyse and exploit the nonlinearities. Analysis and Design of Nonlinear Systems in the Frequency Domain provides clear illustrations and examples at the beginning and the end of each chapter, respectively, making it of interest to both academics and practicing engineers.
